Synthetic Biology of Parts: Goals

Understand how to build with atomic precision on increasing length scales (to 100 nm and beyond)

Understand how to build sophisticated molecular devices that rival those from Nature

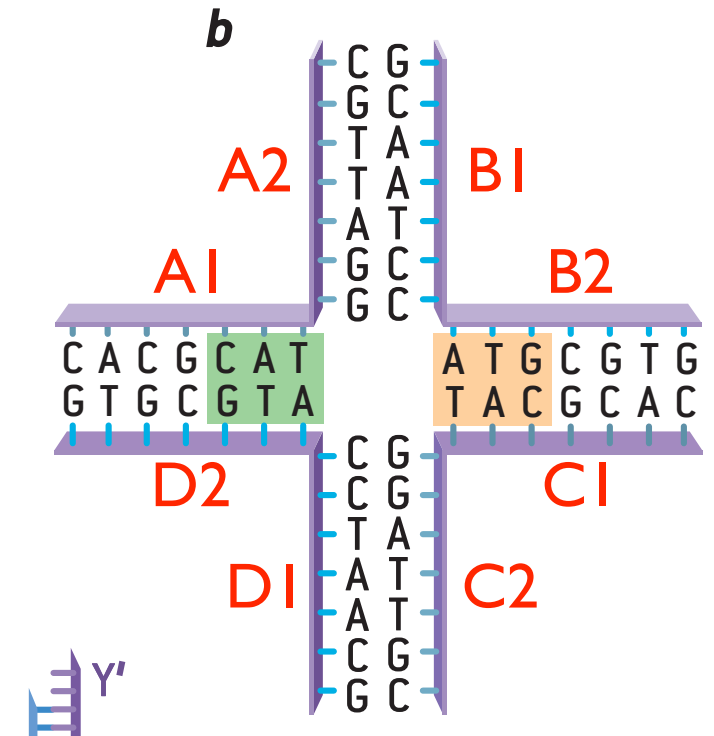

Construct and deploy useful said devices
e.g. tools for biophysics, diagnostics, therapeutics
communication, computing, energy, etc.

THE STRUCTURE OF DNA

DNA is a nanoscale structure, consisting of a double backbone of phosphate and sugar molecules between which complementary pairs of bases (A and T; C and G) are connected by weak bonds (*left*). DNA's most common conformation is B-DNA (*center*), which twists in a right-handed double helix about two nanometers in diameter. One full turn of the helix is about 3.5 nanometers, or 10 to 10.5 base pairs long. In special circumstances DNA can form a left-handed double helix called Z-DNA (*right*).
